### Lesson 05 Demo 05

# Using a Pretrained Model to Create an Application Structure

**Objective:** To create a pre-trained model for generating an application structure based on

the type of application

Tools required: GitHub Copilot

Prerequisites: Basic knowledge of programming languages

#### Steps to be followed:

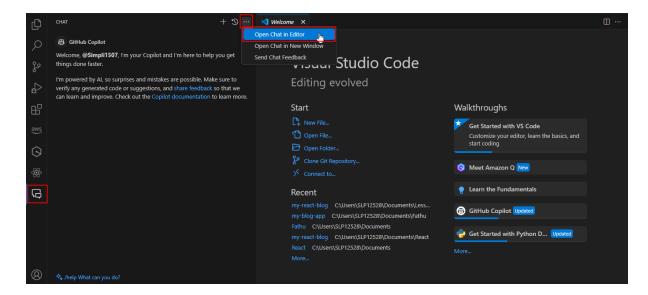

1. Create a pretrained model using GitHub Copilot

2. Run the code using GitHub Copilot

**Note:** Please be advised that GitHub Copilot is an artificial intelligence tool that can produce varied outputs even when presented with similar prompts. Thus, you may get different code snippets for the same prompt.

## Step 1: Create a pretrained model using GitHub Copilot

1.1 Click on the **Chat** icon, click on the **three dots** icon, and select the **Open Chat in Editor** option

1.2 Use the following prompt to create a pretrained model class **MyStructureGenModel** that generates an application structure:

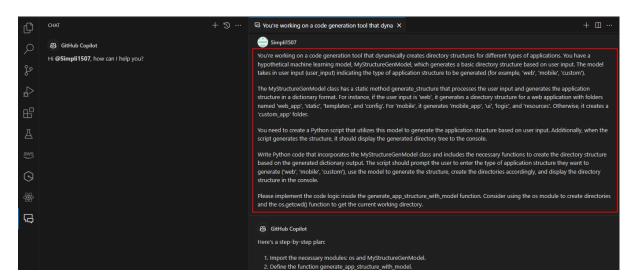

You're working on a code generation tool that dynamically creates directory structures for different types of applications. You have a hypothetical machine learning model, MyStructureGenModel, which generates a basic directory structure based on user input. The model takes in user input (user\_input) indicating the type of application structure to be generated (for example, 'web', 'mobile', 'custom').

The MyStructureGenModel class has a static method generate\_structure that processes the user input and generates the application structure in a dictionary format. For instance, if the user input is 'web', it generates a directory structure for a web application with folders named 'web\_app', 'static', 'templates', and 'config'. For 'mobile', it generates 'mobile\_app', 'ui', 'logic', and 'resources'. Otherwise, it creates a 'custom app' folder.

You need to create a Python script that utilizes this model to generate the application structure based on user input. Additionally, when the script generates the structure, it should display the generated directory tree to the console.

Write Python code that incorporates the MyStructureGenModel class and includes the necessary functions to create the directory structure based on the generated dictionary output. The script should prompt the user to enter the type of application structure they want to generate ('web', 'mobile', 'custom'), use the model to generate the structure, create the directories accordingly, and display the directory structure in the console.

Please implement the code logic inside the generate\_app\_structure\_with\_model function. Consider using the os module to create directories and the os.getcwd() function to get the current working directory.

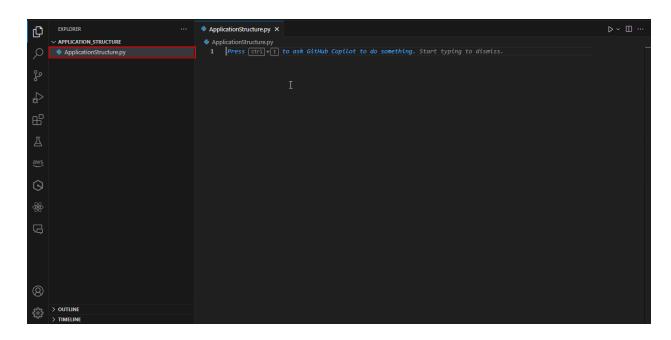

```
& GitHub Copilot
           Hi @Simpli1507, how can I help you?
                                                                                                                          def generate_structure(app_type):
    if app_type == 'web':
                                                                                                                                       return {
    'web_app': ['static', 'templates', 'config']
                                                                                                                          # Prompt the user to enter the type of application structure
user_input = input("Enter the type of application structure to generate ('web', 'mobile', 'custom')
뎏
                                                                                                                          # Generate the directory structure
dir_structure = MyStructureGenModel.generate_structure(user_input)
                                                                                                                           cwd = os.getcwd()
           Hi @Simpli1507, how can I help you?
                                                                                                                           # Create directories based on the generated structure
for dir, subdirs in dir_structure.items():
                                                                                                                                 main_dir_path = os.path.join(cwd, dir)
                                                                                                                                  os.makedirs(main_dir_path, exist_ok=True)
                                                                                                                                  for subdir in subdirs:
                                                                                                                          # Display the directory structure
print("Generated directory structure:")
for dir, subdirs in dir_structure.items():
                                                                                                                                 print(f"{dir}/")
for subdir in subdirs:
    print(f" {subdir}/")
                                                                                                                    if __name__ == "__main__":
    generate_app_structure_with_model()
습
                                                                                                                  This code will create the directories and subdirectories in the current working directory and print the structure to the console. The exist_okeTrue_argument in os_makedirs_ensures that the function does not raise an error if the directory already exists.
```

Note: Copy the generated code and save it in the Notepad for the next steps

### Step 2: Run the code using GitHub Copilot

2.1 Create a new file named **ApplicationStructure.py**, as shown in the screenshot below:

2.2 Paste the following generated code in the **ApplicationStructure.py** file, as shown in the screenshot below:

import os

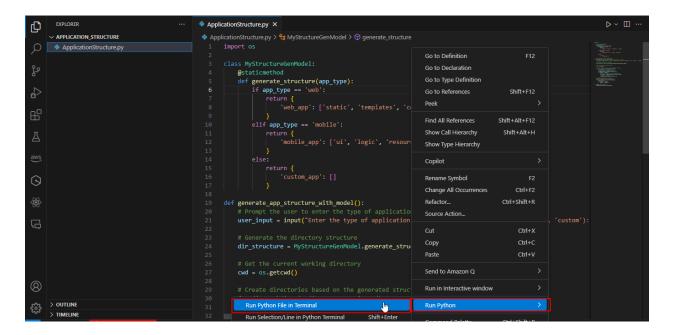

```
class MyStructureGenModel:
    @staticmethod
    def generate_structure(app_type):
        if app_type == 'web':
            return {
                'web_app': ['static', 'templates', 'config']
        }
        elif app_type == 'mobile':
            return {
                      'mobile_app': ['ui', 'logic', 'resources']
        }
        else:
        return {
                     'custom_app': []
        }
}
```

```
def generate_app_structure_with_model():
  # Prompt the user to enter the type of application structure
  user_input = input("Enter the type of application structure to generate ('web',
'mobile', 'custom'): ").strip().lower()
  # Generate the directory structure
  dir_structure = MyStructureGenModel.generate_structure(user_input)
  # Get the current working directory
  cwd = os.getcwd()
  # Create directories based on the generated structure
  for dir, subdirs in dir_structure.items():
    # Create the main directory
    main dir path = os.path.join(cwd, dir)
    os.makedirs(main_dir_path, exist_ok=True)
    for subdir in subdirs:
      # Create the full path for the subdirectory
      full path = os.path.join(main dir path, subdir)
      # Create the subdirectory
      os.makedirs(full_path, exist_ok=True)
  # Display the directory structure
  print("Generated directory structure:")
  for dir, subdirs in dir structure.items():
    print(f"{dir}/")
    for subdir in subdirs:
      print(f" {subdir}/")
if name == " main ":
  generate_app_structure_with_model()
```

```
ApplicationStructure

ApplicationStructure
```

2.3 Save the file, right-click on the editor, click on **Run Python**, and then click on **Run Python File in Terminal**, as shown in the screenshot below:

2.4 Enter **web** to specify the type of application structure you want to generate, as shown in the screenshot below:

```
ApplicationStructure;  
Applic
```

The application structure will be generated in the folder list.

2.5 Click on the web\_app to view the application structure, as shown in the screenshot below:

You will see the following interface:

2.6 Execute the **ApplicationStructure.py file** and input **mobile** to select the type of application structure you wish to generate, as depicted in the screenshot below:

2.7 Click on **mobile\_app** to view the application structure, as shown in the screenshot below:

By following these steps, you have successfully created a pretrained model for generating an application structure based on the type of application.
